Radiation maps

Quality of the regression

Aim

Long time series of the total radiation emitted by the Earth, for the purpose of climate studies

- ▶ Total radiation (SW+LW) measured by wide field-of-view radiometer, $W m^{-2}$
 - ▶ Operated much longer than scanner
 - ▶ sw filter suffers from ageing
- ▶ **Monthly averages**
- ▶ Coverage in time and space: +81° to -81° latitude, November 1978 to September 1999 (nearly 21 years)
- ▶ Disadvantages: cannot study cloud forcing, TOA albedo; low spatial resolution
- ▶ Compared to former work: want to use more recent models and processing techniques

Nonscanner on board ERBS

- ▶ 2 wide field-of-view radiometers:
 - ▶ one radiometer for SW: 0.2 to 5 μm
 - ▶ one radiometer for TW: all wavelengths
- ▶ 2 medium field-of-view radiometers

- ▶ Three sun-synchronous satellites with an inclination $\approx 99^\circ$: NIMBUS-7 (11 am), NOAA-9 (2.30 pm), NOAA-10 (7.30 pm)
- ▶ One precessing satellite: ERBS (inclination $\approx 57^\circ$)
- ▶ Instantaneous (4-second) measurements from SEFDT and MWDT datasets

Extending TOA radiation to 1978

RMIB

Introduction

Aim & justification

Data sources

Modelling

Assumptions & limitations

Procedure

Results

Radiation maps

Quality of the regression

- ▶ We assume the spectral response of the total wave (TW) measurement is sufficiently flat
- ▶ No intercalibration of different satellites (except common reference altitude)
- ▶ For the moment: albedo independent of solar zenith angle

Obtaining the monthly average flux

Extending TOA radiation to 1978

RMIB

Introduction

Aim & justification

Data sources

Modelling

Assumptions & limitations

Procedure

Results

Radiation maps

Quality of the regression

Starting from instantaneous measurements from the WFOV radiometer:

- ▶ Conversion of datafiles from native format to NETCDF
- ▶ Processing the raw measurements
- ▶ Binning in $5^{\circ} \times 5^{\circ}$ bins
- ▶ Regression of the diurnal model on the data
- ▶ Numerical integration of the **monthly average** diurnal model from 0 to 24 hours
- ▶ Checks on the quality of the regression and final output

Elimination of direct sunlight

Extending TOA radiation to 1978

RMIB

Introduction

Aim & justification

Data sources

Modelling

Assumptions & limitations

Procedure

Results

Radiation maps

Quality of the regression

- ▶ Not using solar zenith angle: seems to throw away good measurements without taking into account solar eclipse by Earth disc
- ▶ But using geometric technique
 - ▶ Takes into account angle between spacecraft, Earth and sun
 - ▶ Takes into account solar eclipse by Earth (ellipsoid shape with GRS80 parameters)

Regression of the diurnal model

Model equation and example (Sahara region)

Procedure

Results

Radiation maps

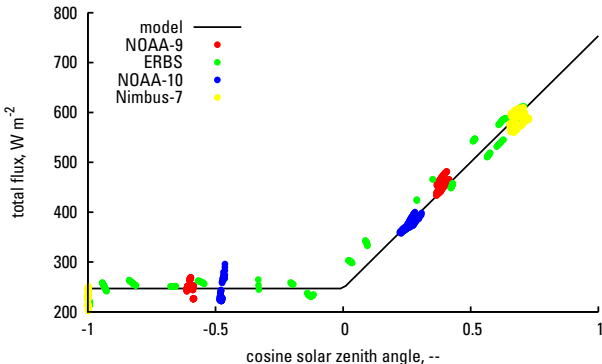

Quality of the regression

$$F(t) = \begin{cases} p_0 + p_1 \cos z(t) & \text{if } \cos z > 0 \\ p_0 & \text{otherwise} \end{cases}$$

Regression of diurnal model on WFOV measurements

$0 < \text{longitude} < 5$

$20 < \text{latitude} < 25$

Regression of the diurnal model

Why a diurnal model in terms of solar zenith angle?

Extending TOA
radiation to 1978

RMIB

Introduction

Aim & justification

Data sources

Modelling

Assumptions &
limitations

Procedure

Results

Radiation maps

Quality of the regression

- ▶ Solar zenith angle at noon varies considerably, depending on season and latitude
- ▶ Corollary: even measurements at fixed local time lead to a range of zenith angles, which is better for the regression
- ▶ Regression of a linear two-parameter model is the obvious approach when only heliosynchronous data with two measurements per day are available
- ▶ Can estimate baseline (night-time) flux without night-time measurements

Disadvantage:

- ▶ Limited range of the independent variable at high latitudes

Numerical integration of the diurnal model

Example (Sahara region)

Extending TOA radiation to 1978

Procedure

Results

Radiation maps

Quality of the regression

Monthly average diurnal model and WFOV measurements
 $0 < \text{longitude} < 5$
 $20 < \text{latitude} < 25$

Checks on the quality of the regression

Values can be rejected for several reasons

Extending TOA
radiation to 1978

RMIB

Introduction

Aim & justification

Data sources

Modelling

Assumptions &
limitations

Procedure

Results

Radiation maps

Quality of the regression

1. An error occurred during fitting (e.g., too many iterations in Levenberg-Marquardt)
2. Regression as a whole is not significant
3. Regression is useless according to the Box criterion (explains less than the error)
4. Null hypothesis cannot be rejected for at least one of the parameters
5. At least one parameter is nonphysical (e.g., negative night-time flux)
6. Numerical integration cannot be performed for numerical reasons
7. Resulting average flux is nonphysical (i.e., negative)

Quality of the regression

An example of a good regression

$$R^2 = 0.98$$

Regression of diurnal model on WFOV measurements
0 < longitude < 5
20 < latitude < 25

Partially sunlit at sunrise/sunset transition

$$R^2 = 0.96$$

Regression of diurnal model on WFOV measurements
70 < longitude < 75
50 < latitude < 55

Zenith angle dependence over ocean surface

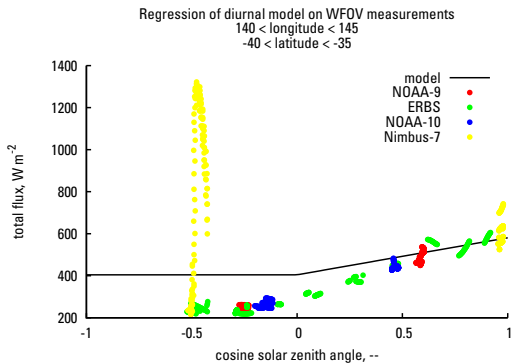

$$R^2 = 0.91$$

Regression of diurnal model on WFOV measurements
60 < longitude < 65
-30 < latitude < -25

A very poor regression

$R^2 = 0.05$ with NIMBUS-7 data, $R^2 = 0.96$ without

Estimate intercept with daytime measurements only

$$R^2 = 0.99$$

Regression of diurnal model on WFOV measurements
80 < longitude < 85
-80 < latitude < -75

Modified diurnal model during polar winter

$s^2 = 37705$ with NIMBUS-7 data, $s^2 = 91$ without

Regression of diurnal model on WFOV measurements
-45 < longitude < -40
75 < latitude < 80

Conclusions

Extending TOA radiation to 1978

RMIB

Introduction

Aim & justification

Data sources

Modelling

Assumptions & limitations

Procedure

Results

Radiation maps

Quality of the regression

- ▶ Revived the old NIMBUS-7 and less older ERBE data
- ▶ WFOV measurements do contain usable spatial information
- ▶ Made TOA radiation maps over nearly 21 years (November 1978 – September 1999) and nearly the entire globe, sometimes with scarce data
- ▶ Problems remain: stray light? diurnal models inappropriate?

Future work

Extending TOA radiation to 1978

RMIB

Introduction

Aim & justification

Data sources

Modelling

Assumptions & limitations

Procedure

Results

Radiation maps

Quality of the regression

- ▶ Incorporate more recent measurements (GERB, CERES)
- ▶ Better filtering of the data
- ▶ Improve diurnal models
- ▶ Applications: e.g. volcanic eruptions (El Chichón 1982, Pinatubo 1991)
